

The completed 1B arm uses $d = 3$ signal coordinates in EVERY existing cell: M varies the number of pure-noise columns only. Cells whose population gap is NOT_IDENTIFIED are OMITTED from panel (a), NOT assigned zero; a blank is not a zero. Markers are means over cells; error bars are standard errors, smaller than the marker in every cell here so no bar is visually separable from its marker (post-review finding 4). Representation loss and learner shortfall are never combined.
